

Description of Tasks for SPRINT 4

Sprint 4 involves the development of an app using Ionic (and Angular) that must contain at least 6 screens with the functionalities listed and described below.

1. User Registration Screen

- On this screen, users will be able to register using Firebase.
- To be able to register users in Firebase from the Ionic app, it will be necessary to use the Authentication service that this backend includes.
- Although Firebase supports various authentication methods, users must be able to register using their email and password at a minimum.
- The email and password required to register must be entered by the user using a form included on this screen.
- In addition to the email and password required for registration, this screen must also include some additional information, at a minimum, this could be the user's first and last name as well as an image of the user.
- This information associated with the user's profile must be stored in the Firebase database.

2. User Authentication Screen

- On this screen, users will be able to authenticate (log in) against Firebase.
- Although Firebase supports various authentication methods, users must be able to log in using an email and password at a minimum.
- The email and password needed to log in must be entered by the user using a form included on this screen.

3. Favorites Screen

- This screen should display (as a list) each of the items from at least one of the collections available in Firebase (which can be the same ones used in development with Angular).
- This screen should also indicate in some way (for example, with an identifying label or a different color) which of all the elements from the list obtained from Firebase are favorites.
- The elements selected as favorites from those shown on the list on this screen will not be obtained from Firebase but from the SQLite database directly, which an Ionic app allows to use when it is run on a real mobile device or an emulator of the same.
- Only logged-in users will have access to this favorites screen.
- On this screen, the user will be able to click on any of the items from the chosen collection to go to the detail screen of that item.

4. Detail Screen

- This screen should display the details of the selected item from the Firebase collection chosen to be shown on the screen with the complete list.
- The information to be displayed can be any that is associated with the selected item from the collection, although at a minimum, it should include some information that characterizes each item.
- In addition to displaying any extra information desired, at a minimum, a characteristic image representing the selected item from the collection should be displayed.
- This detail screen should also include a button where the user can click to include this item among their favorites (or if it already is, to remove it from them). To implement this functionality, the SQLite database that an Ionic app allows to use when it is run on a real mobile device or an emulator of the same must be used.
